Outline

- 2 Using NST
 - Fixtures
 - Test groups
 - Tests
 - Criteria
 - Customizing criteria
- Inside NST
 - The basic idea
 - Early implementations, and other lessons
 - How it maybe should work

Conclusion

∃ ► < ∃ ►</p>

What is unit testing?

From wikipedia:

Unit testing is a software verification and validation method where the programmer gains confidence that individual units of source code are fit for use.

- "Unit" refers to the basic elements of program design procedures, functions, classes, etc.
- Unit tests should be independent of each other.
- Typically written by the programmer.
- Also usable as regression tests.

Unit testing Te Using NST Te Inside NST C Conclusion C

Basic concepts

Fixtures

• Named data values to which we apply tests.

Groups

Collections of tests.

Tests

• One application of a criterion to values, usually to fixtures.

Criteria

• Named process of verification.

イロト イポト イヨト イヨト

Fixtures Test groups Tests Criteria Customizing criteria Running NST

A simple NST example

Define two fixtures.

```
(def-fixtures simple-fixture
    (:documentation "Define two bindings")
  (magic-number 120)
  (magic-symbol 'asdfg))
(def-test-group simple-test-group
    (simple-fixtures)
  (def-test has-num
      (:eql magic-number)
    (factorial 5))
  (def-test has-sym
      (:eq magic-symbol)
   'asdfh))
```

 (car '(a b c)))
```

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Fixtures Test groups Tests **Criteria** Customizing criteria Running NST

Predicates and transformations

Boolean-valued functions can be used as test criteria:

(def-test pred1 (:predicate numberp) 3)

Forms can be altered before testing:

```
(def-test applycheck
    (:apply cadr (:eql 10))
    '(0 10 20))
```

ヘロト ヘアト ヘビト ヘビト

1

List criteria

Expect every element of a list to pass a criterion:

Apply different criteria to respective elements:

<ロ> <同> <同> < 回> < 回> < 回> < 回> < 回> < 回</p>

Fixtures Test groups Tests **Criteria** Customizing criteria Running NST

Information and warnings

Additional information for results:

```
(def-test known-bug
  (:info "Known bug" (:eql 3))
  4)
```

Passing with a warning:

```
(def-test known-bug
   (:warn "~d is not a perfect square" 5)
5)
```

ヘロト 人間 ト くほ ト くほ トー

Fixtures Test groups Tests Criteria Customizing criteria Running NST

Compound criteria

Negating another criterion:

```
(def-test not1 (:not (:symbol b)) 'a)
```

Passing all of a set of criteria:

```
(def-check not1 ()
   (:all (:predicate even-p)
                (:predicate prime-p))
2)
```

And similarly, : any for at least one of a set of criteria.

くロト (過) (目) (日)

Fixtures Test groups Tests Criteria Customizing criteria Running NST

Let's argue about multiple values!

In Lisp:

- Functions can return multiple values.
- But paying attention to the "extras" is optional.
- Accessing "extras" takes a little extra effort.

In NST

- Even if they're ingorable, extra values must be *correctly implemented*.
- So when validating a function, NST expects all values to be accessed (and presumably validated).
- Ignoring "extras" takes a little extra effort.
- A mismatch between the received and expected values is an error.

Multiple-values and multiple-argument predicates

Multiple values are handled as additional arguments to the functions underlying criteria:

Other criteria

For a full list of criteria, see the manual.

- Additional basic checks.
- :err expecting an error.
- :permute list permutation.
- Simple checks for vectors, slots.
- :perf timing form evaluation.

Fixtures Test groups Tests Criteria **Customizing criteria** Running NST

Defining new criteria

NST provides three macro-style mechanisms for defining a new criterion:

- By describing how it translates to another criterion.
- By describing how it maps values to a results expression.
- By describing how it maps a form (which would evaluate to a list of values) to a results expression.

In fact, all of the built-in criteria use one of these three mechanisms.

Fixtures Test groups Tests Criteria **Customizing criteria** Running NST

Defining new criteria

By translation:

- By a map from values to a results expression: :true,
 - :eql, :predicate, :info.
- By a map from a form to a results expression: :not, :perf, :err.

The basic idea Early implementations, and other lessons How it maybe should work

A little bit of background

A number of Lisp language features greatly simplified writing NST.

- Macros.
- Compile-time code execution.
- Multiple inheritance.
- Sophisticated method dispatch.

The basic idea Early implementations, and other lessons How it maybe should work

The top-level NST forms all defined by macros:

- Components not evaluated, but rewritten into other forms which (may be) evaluated.
- The typical Lisp way of writing language extensions.
- Allows a direct specification of the test.

The basic idea Early implementations, and other lessons How it maybe should work

Compile-time code execution

Part of the macro-expansion of tests involves translating criteria into Lisp code.

- Criteria definitions expand to method definitions.
- So macro-expanding tests involves running Lisp at compile-time.
- Moreover, the required routines may be found in the same code file as the tests they help to expend.

The basic idea Early implementations, and other lessons How it maybe should work

Multiple inheritance

Lisp classes may have more than one superclass, and moreover may inherit method implementations from different superclass hierarchies.

• Unlike e.g. Java, where all but one superclass hierarchies may define only abstract methods.

NST uses multiple inheritance for fixture application.

- Fixtures, groups and tests all translate to classes.
- Fixtures make their bindings via methods of their class.
- Groups' and tests' classes are subclasses of the classes corresponding to the fixtures they apply.
- So they inherit the fixture-binding methods.

The basic idea Early implementations, and other lessons How it maybe should work

Dynamic variable scope

Lisp offers both dynamic and static scoping for local variables.

- Determine the rules as to how we know what value-binding a program variable should have.
- If this idea is new to you, then you're probably used to static scope rules.
- Simple dynamic scoping example:

```
(defun print-x ()
  (declare (special x))
  (write x))
(defun x-as-3 ()
  (let ((x 3))
     (declare (special x))
     (print-x)))
```

ヘロン 人間 とくほど くほとう

The basic idea Early implementations, and other lessons How it maybe should work

Method dispatch

Lisp has a very rich notion of method dispatch.

- Typically, dispatch chooses exactly one method for a particular object.
- In Lisp, there are many available *method combinations* to map a method invocation to some assemblage of the corresponding method definitions.
 - "Standard" principle method override.
 - "Around" methods wrap other methods.
 - "Before" and "after" methods.
 - Sequential execution of several methods, and various ways of combining their results.

The basic idea Early implementations, and other lessons How it maybe should work

Around-methods

Used with dynamic scoping rules for fixture definitions:

```
(def-fixtures simple-fixture ()
  (magic-number 120) (magic-symbol 'asdfg))
```

becomes something like:

```
(defmethod run-group :around ((gr simple-fixtures))
  (let ((magic-number 120) (magic-symbol 'asdfg))
     (declare (special magic-number magic-symbol))
     (call-next-method)))
```

《曰》《御》《臣》《臣》 [臣]

The basic idea Early implementations, and other lessons How it maybe should work

Before- and after-methods

Used for : setup and : cleanup arguments:

becomes, in part, something like:

```
(defmethod run-test :before ((test sc))
  (setf for-setup 2))
(defmethod run-test :after ((test sc))
  (setf for-setup 1))
```

ヘロン 人間 とくほ とくほ とう

The basic idea Early implementations, and other lessons How it maybe should work

Fwrappers are a Allegro Common Lisp feature.

- Like an around-method for non-generic functions.
- Useful for extending third-party code, etc.
- But for code we're writing ourselves, no clear advantage over around-methods.

The basic idea Early implementations, and other lessons How it maybe should work

Gensym abuse

In one version, NST solved potential name conflicts by naming almost all intermediate structures via gensym.

- Very effective at avoiding accidental name conflicts.
- Very secure against interference with testing internals.
- Very secure against debugging.
- Very secure against examination and understanding.
- Very secure against extension.

The basic idea Early implementations, and other lessons How it maybe should work

Static class data

NST must be able to retrieve information associated with fixtures, groups and tests.

- We compile fixtures, groups and tests to classes.
- We'd prefer this information to be available *statically*, with reference to the class but without necessarily referencing a particular object.

The basic idea Early implementations, and other lessons How it maybe should work

Static class data

With :static allocation for class slots, accessors still require an object instance.

We'd like a way to store & retrieve class data *without* an object instance.

The basic idea Early implementations, and other lessons How it maybe should work

Class metaobjects for static class data

One approach we tried was via the metaclass.

- Lisp models a program's structures via standardized Lisp objects.
- By default, the definition of a class is stored in an instance of standard-class.
- But we can extend standard-class, and include static data as fields in the metaclass.

```
(defclass mzz (standard-class)
 ((aaa :accessor zzz-aaa)))
(defclass zz () ()
 (:metaclass mzz))
(setf (zzz-aaa (find-class 'zz)) 5)
```

Prefer object prototypes

We later discovered the preferred style of using *class prototypes*.

ヘロン 人間 とくほ とくほ とう

э.

The basic idea Early implementations, and other lessons How it maybe should work

NST internal packages

Fixtures correspond to two classes:

- One with methods for applying fixtures to a group once.
- One with methods for applying fixtures individually to each test within a group.

Right now, we create a name for this class.

```
(def-fixtures pkg::gname |# ... |#
```

becomes (in part) something like

```
(defclass nst-fixture-test-class-names::pkg///gname
        () ())
```

・ロト ・ 理 ト ・ ヨ ト ・

The basic idea Early implementations, and other lessons How it maybe should work

Package abuse?

We would not need special packages for internal class names if the classes simply didn't have names.

- By using MOP function calls directly (as opposed to defclass) one can create *anonymous* classes.
- The internal classes themselves can be made available as static information of the reference class.

The basic idea Early implementations, and other lessons How it maybe should work

A MOP-like model

Not just macros, but also functions.

- À la defclass and ensure-class.
- Also suggests: multiple "front-ends" (macros) translating to the single backend.

The basic idea Early implementations, and other lessons How it maybe should work

Error reporting

Is there actually any programming tool where "improve error messages" is *not* on the to-do list?

- Errors arising from bad use of criteria (such as treating a list with a vector criterion) are not clearly marked as testing errors, rather than test failures.
- General difficulty in good error analysis.

The basic idea Early implementations, and other lessons How it maybe should work

QuickCheck originated in Haskell as a framework for generating randomized tests of programmer-stated program invariants.

- (equal (reverse (reverse x)) x)
- (if (< x y) (eql (max x y) y))

Some version of QuickCheck might be useful in NST.

- Side-effects
- Cannot rely on types for direction.

ヘロン 人間 とくほ とくほ とう

The basic idea Early implementations, and other lessons How it maybe should work

Further integration

- Better control of NST options through ASDF.
- Automated XML/JUnit output.
- Other output formats.

If you want to really learn Lisp...

Writing a unit tester is an effective way to see many interesting areas of Lisp!

- Subtle macro authoring.
- Evaluation-time issues.
- Under the hood of the class system.

・ 同 ト ・ ヨ ト ・ ヨ ト

Is this actually unit testing?

Returning to wikipedia's definition of unit testing:

A unit is the smallest testable part of an application. In procedural programming a unit may be an individual program, function, procedure, etc., while in object-oriented programming, the smallest unit is a class, which may belong to a base/super class, abstract class or derived/child class.

- Is our unit the expression?
- Is there a more natural way to structure tests around the unit of a function?
- Lisp is *also* object-oriented should a Lisp unit test package offer a more natural framework for classes and methods?

Proof in the practicality

Future directions aside, we believe that NST is now, already, a useful tool.

- Has been used on several large projects already.
 - The SHOP2 planner.
 - A plan recognizer.
 - Language interpreter.
 - Security software.
- Reasonable mature and solid.
- Actively maintained.
- Open-sourced.
